RESEARCH TASK

INTRODUCTION

As a system administrator managing user accounts within Active Directory is a crucial task but also takes a lot of time. As the company or organizations grow, the number of users also increases, making manual user management difficult and increasing the chances of errors. In this, we will explore the automation of Active Directory user management using PowerShell which will focus on tasks such as adding, updating, enabling disabling, and deleting user accounts and sending an Email to a related person stating that the requested task has been done.

Additionally, there are many other system security-related tasks such as malware scans, managing firewall rules, performing system audits, monitoring system logs, updating the system, taking backups, optimization of resource allocation, preventing system downtime, checking for software updates, tuning the system performance and tech support - troubleshooting. All these tasks are essential for maintaining the security and integrity of the system and take a lot of time. we can manage all that with the use of PowerShell and automating them can ensure that they are performed on time regularly and with consistency.

This research task shows the difficulties in managing AD and suggests that PowerShell scripting can be used to effectively automate and optimize these procedures as discussed by (Company, 2023).

1. MANUAL USER MANAGEMENT

Manual user management in AD involves going through many admin tools and interfaces like ADUC or PowerShell cmdlets, system admin must perform tasks such as creating, updating, and enabling new user accounts and modifying related attributes, and the offboarding process involves disabling or deleting accounts as per the requirements of the organization and notifying HR about these changes.

CHALLENGES PRESENTED BECAUSE OF MANUAL USER MANAGEMENT

- <u>Time-consuming</u>: as organizations grow number of users increases and adding them one by one is a noticeably big challenge due to the time it takes to do user-related tasks.
- <u>Error-possibilities</u>: with manual work human error happens such as typing wrong e-mail addresses or incorrect entries which can lead to issues such as misconfigured user accounts or service disruption, Issues such as unauthorized access can also arise from it.
- <u>Inconsistency</u>: Manual processes might lead to inconsistencies in user configuration across the AD environment, leading to operational issues such as deleting or disabling the wrong user account or adding data to different users with the same name.
- <u>Scalability problems</u>: for a large-scale deployment manual user management becomes impractical it is also difficult for organizations with frequent staff changes.
- <u>Sending E-mail</u>: Once a new user has been added, updated, or deleted from ADUC as per requirements system admin also has to inform the related authority that the required task has been done and if you are adding 2-3 users then it might not feel like an issue but if you are adding many users in one day then sending so many emails can be a time-consuming and challenging task.

2. SECURITY MANAGEMENT

It takes time and effort to perform security-related, optimization-related, or compliance-checking chores manually. In addition, there's a chance the system administrator forgot to complete these duties or was too preoccupied with other work at the time. Users must be informed about several of these duties that may have an impact on them. Tasks including system audits, firewalls, log monitoring, data backups, update management, preventing system outages, infrastructure scalability, regulatory compliance, optimizing system performance, and troubleshooting can also be included.

CHALLENGES PRESENTED BECAUSE OF MANUAL SECURITY MANAGEMENT

- <u>Malware Scanning</u>: Malware scanning is essential for maintaining security, and manually doing it lacks consistency which may result in issues later on.
- <u>Firewall Management</u>: Firewalls are the most critical components of network security; manually managing firewall rules to block incoming traffic on a specific port creates a security issue.
- <u>System Auditing and Log Monitoring</u>: Regular system audits and monitoring can help detect unusual activity that can catch security breaches and log monitoring can provide information about system activities and help identify incidents manually doing these things can take time and mistakes might lead to security risks.
- <u>System Updates:</u> keeping the system updated is most important for security as updates include security patches and manually doing them leads to issues related to security as the system admin can miss if too busy or out of the office.
- <u>Data-Protection</u>: Regular backups can help ensure that important data can be recovered during an incident and doing this manually creates huge risks.
- <u>Prevent system downtime</u>: The system admin has to manually add information in the task scheduler and it's also time-consuming to send emails to users who might be affected.
- <u>Regulation compliance</u>: The system admin also needs to make sure that everything is as per regulations, checking all of the tasks requires a lot of time.
- <u>Performance Tuning and Resource optimization</u>: This involves checking if all the resources are used correctly and manually checking it takes time.
- <u>Technical support and Troubleshooting</u>: There are many critical issues the system admin has to face in troubleshooting, there are many services like printers and servers, and manually checking everything is time-consuming.

In Summary, Automation will be able to improve the accuracy, efficiency, and consistency of user management and security management, and also improve and free system admins to focus on other tasks.

RESEARCH SOLUTION

POWERSHELL

This research solution automates tasks with PowerShell, optimizes workflows to boost output, fortifies security, and ensures legal compliance. A method for email automation is also included in the solution, and it's utilized to inform relevant parties about the progress of different activities. System administrators find PowerShell to be an indispensable tool due to the substantial time savings, fewer errors, and enhanced system performance and stability that result from automating these activities.

<u>User Management</u>: It is possible to automate user administration tasks with PowerShell cmdlets. For instance, use the New-ADUser cmdlet to add a new user to Active Directory (AD). Options like -Name, -GivenName, -Surname, -EmailAddress, and others are accepted. -Explanation, -UserPrincipalName,-SamAccountName, -Office, -Workplace Phone -Country of Work, Use -Enabled, and -AccountPassword to fully configure the new user.

<u>Security Management</u>: Security tasks such as malware scanning can be automated using the Start-MpScan cmdlet, which initiates a malware scan. Firewall rules can be managed using the New-NetFirewallRule cmdlet.

Email AutomationUsing the Sendemailuseradd function, an automatic email is sent to HR following the completion of user-related actions. The Net.Mail is used by this function.Send an email using the SmtpClient class. The SMTP server name, port, and the EnableSsl attribute are used to instantiate the SmtpClient class, and it is set to true.

A PSCredential object, which is generated with the sender's email address and an app-specific password, is what the Credentials field of the SmtpClient object is set to. The ConvertTo-SecureString cmdlet is used to transform the app-specific password into a secure string.

Data Protection: Data can be copied between locations using the Copy-Item cmdlet, which essentially creates a backup of the original file. The parameters -Path, - Destination,-Recurse, and -Force are accepted by this cmdlet.

Resource Management: System resources, such as memory, can be monitored to optimize resource allocation. The Win32_OperatingSystem class and the Get-WmiObject cmdlet can be used to accomplish this, retrieving details about the operating system, including free physical memory.

System Downtime Prevention: The Register-ScheduledTask cmdlet can be used to schedule system reboots. The -Action, -Trigger, -TaskName, and -Description options are accepted when using this cmdlet to create a new scheduled task.

<u>Software Updates Management</u>: To find out what software updates are available, use the Get-WindowsUpdate cmdlet. These updates can then be installed using the Install-WindowsUpdate cmdlet. The PSWindowsUpdate contains these cmdlets.

Infrastructure Scalability Planning: By keeping an eye on system resources like CPU utilization, infrastructure scalability may be planned. To obtain performance counter information, including processor time, use the Get-Counter cmdlet.

<u>Compliance Checks</u>: Encrypting data allows one to verify compliance with requirements. Although there isn't a built-in cmdlet for this in PowerShell, it is possible to write a custom function to verify if data at rest is encrypted.

Performance Tuning: Process priority can be changed to fine-tune system performance. A list of all processes that are currently executing can be obtained using the Get-Process cmdlet, and each process PriorityClass attribute can be changed as necessary.

Technical Support and Troubleshooting: By using the Get-Service cmdlet to provide information about a service and its dependencies and the Get-WinEvent cmdlet to search event logs for related occurrences, technical help and troubleshooting may be automated.

In conclusion, PowerShell offers a stable basis for automating several kinds of system administration work. Administrators can increase security, check regulatory compliance, optimize workflows, and increase efficiency by utilizing particular PowerShell cmdlets. Significant time savings, a decrease in errors, and enhanced system stability and performance can all result from this.

Figure 1(Premium Vector | System Administrator, 2021)

WORK-FLOW

The flow chart demonstrates the working of the PowerShell script that solves problems by automating the described tasks which saves time and reduces errors.

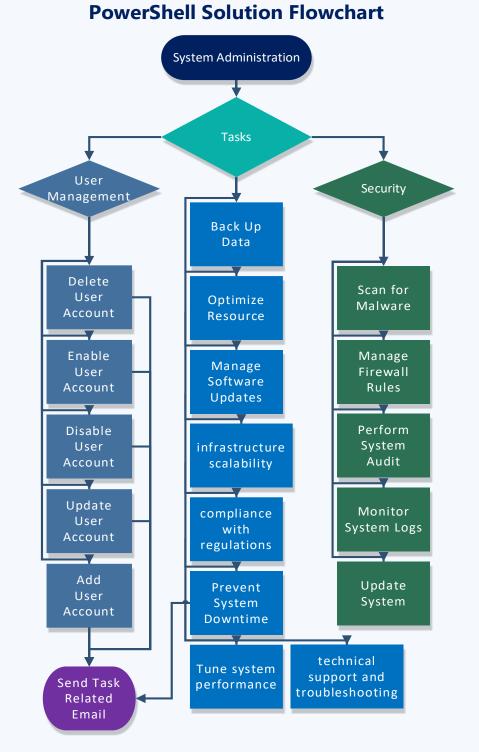

Figure 2PowerShell code working flowchart.

POWERSHELL AUTOMATION PRESENTATION OF WORKING SCRIPT

SECURITY MANAGEMENT

Once the script is executed it will import all the necessary modules and install modules as per requirements. The script will show a list of actions that can be achieved by running it.

USER MANAGEMENT

The script will prompt the user to choose from user-related options and will automatically send an email as soon as the function is executed.

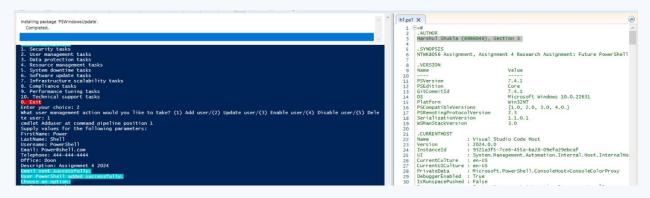

<u>Add User</u>: The script will ask to enter new user details and check if the information is up to standard or not like email and password.

Figure 13 Add user information.

<u>Send Email:</u> Once the user is created email will be sent to HR with the details.

SCRIPT FUNCTIONS INFORMATION TABLE

The function is a block of code that performs a specific task when you execute it.

Table 1. Function Information

Function Name	Purpose	Input Parameters	Output
Adduser	Adds a new user to the Active Directory	FirstName, LastName, Username, Email, Telephone, Office, Description	Confirmation of user addition
Updateuser	Updates an existing user's details in Active Directory	Username, Email, Telephone, Office, Description	Confirmation of user update
Enableuser	Enables a disabled user account in the Active Directory	Username	Confirmation of user enablement
Disableuser	Disables an active user account in the Active Directory	Username	Confirmation of user disablement
Deleteuser	Deletes a user account from the Active Directory	Username	Confirmation of user deletion
Scanmalware	Initiates a malware scan	None	Confirmation of scan completion
Firewallrules	Manages firewall rules	Port	Confirmation of rule management
Systemaudit	Performs a system audit	None	Confirmation of audit completion
MonitorSystemlogs	Monitors system logs	None	Confirmation of log monitoring
Updatesystem	Updates the system	None	Confirmation of system update
Backupdata	Backs up data	None	Confirmation of data backup
Optimizeresource	Optimizes resource allocation	None	Resource allocation status
Preventsystemdowntime	Schedules system reboots to prevent system downtime	None	Confirmation of scheduled reboot
ManageSoftwareUpdates	Manages software updates and patches	None	Confirmation of software update management
Infrastructurescalability	Plans for infrastructure scalability	None	Scalability status
Compliancewithregulations	Ensures compliance with regulations	None	Compliance status
Tunesystemperformance	Tunes system performance	None	Confirmation of performance tuning
TechnicalsupportAndtroubleshooting	Provides technical support and troubleshooting	None	Confirmation of support provision
All Email functions	Sends Email	None (Inbuilt in code)	Confirmation of email sent

POWERSHELL CODE

Script Guide: Code should be able to run given that required modules are installed and with admin rights, just make sure that in the process of sending email, Mail to and Mail from being changed accordingly, and most importantly make sure 16-digit (xxxx xxxx xxxx) app-specific password has been generated by you inside your Gmail from which you are sending your email.

Currently code uses my Gmail app-specific password, to check the code you can only change TO which email address it sends email and keep from as it is, it will send email to your email address from my email address.

Change the path to your liking where paths are assigned.

.DESCRIPTION

This script automates various system administration tasks including security like (scanning for malware,audit,check logs and updates) script also provides user management which included (adding,updating,enabling,disabling and deleting user) and sending email to HR directly from here,it also provides things like data protection, resource management, system downtime prevention,software updates and patch check, infrastructure scalability, compliance, performance tuning, and technical support.

NOTE: Required modules need to be installed and properly configured before running this script and admin access is required.

APPENDIX

A. Definitions

<u>Active Directory (AD)</u>: Windows domain networks can use Active Directory (AD), which was developed by Microsoft as a directory service. Authentication and authorization services are provided, together with a framework for managing and allocating resources in a networked context.

<u>PowerShell</u>: command-line shell and scripting language. With syntax similar to traditional programming languages, users may issue commands, run scripts, and automate operations with this purpose-driven platform for system administration and automation.

<u>Malware</u>: Malware is purposely designed software that aims to harm computer systems or data, interfere with their functioning, or gain unauthorized access. Among the examples are viruses, worms, ransomware, and spyware.

<u>Firewall</u>: Firewalls are network security systems that monitor and control all incoming and outgoing network traffic using pre-established security rules. Its responsibility is to protect reliable internal networks from shady external networks.

<u>System Audit</u>: A system audit is a thorough analysis of the IT infrastructure of a company to determine operational effectiveness, security, and compliance. To find vulnerabilities and guarantee policy compliance.

<u>Data Backup</u>: Making backup copies of your data and having them on hand in case the original is lost or corrupted is known as data backup, backups are useful in case of incident or data corruption.

<u>System Downtime</u>: When a computer system or network is not operating at its best, it is called system downtime. It may be because of maintenance tasks, security events, software bugs, or hardware malfunctions.

<u>Compliance</u>: To follow the rules, laws, norms, and standards that are pertinent to the industry in which a business operates. It guarantees that procedures and systems follow moral and legal standards.

<u>Performance tuning</u>: To increase the speed, effectiveness, and responsiveness of applications and services.

<u>Technical Support</u>: When a user is having issues with hardware, software, or IT systems, technical support provides help and troubleshooting services. Its goal is to fix problems and get everything back to normal.

B. Full Forms

ADUC: Active Directory Users and Computers

CPU: Central Processing Unit

GUI: Graphical User Interface

HTTP: Hypertext Transfer Protocol

HTTPS: Hypertext Transfer Protocol Secure

PS: PowerShell

RAM: Random Access Memory

SMTP: Simple Mail Transfer Protocol

SSL: Secure Sockets Layer

WMI: Windows Management Instrumentation

C. Software used.

Microsoft Visio, Microsoft Word, VS code, Microsoft Excel
